Adversarial Examples:

Small perturbations added to normal inputs can easily fool a deep neural network.

- Perturbations are small, imperceptible to human eyes.
- All networks are vulnerable to adversarial examples.
- Adversarial examples transfer across models.
Deep Neural Network Transformations:

Neural network:

Evolving spaces with transformations:

Krizhevsky et al. 2012, Karen et al. 2013
Understanding Adversarial Subspaces:

1. Non-linear explanation (Szegedy et al. 2013):
Non-linear transformations leads to the existence of small “pockets” in the deep space:
- Regions of low probability (not naturally occurring).
- Densely scattered regions.
- Continuous regions.
- Close to normal data subspace.

2. Linear explanation (Goodfellow et al. 2014):
Adversarial subspaces span a contiguous multidimensional space:
- Small changes at individual dimensions can sum up to significant change in final output: $\sum_{i=0}^{n} x_i + \epsilon$.
- Adversarial examples can always be found if $\epsilon$ is large enough.
Adversarial Attack:

Given input \((x, y)\) and a target class \(l\), the attack generates a new example \(x_{\text{adv}}\), so as to:

\[
\begin{align*}
\text{minimize } & \|x - x_{\text{adv}}\|_p \\
\text{subject to } & f(x_{\text{adv}}) \neq f(x) \text{ or } f(x_{\text{adv}}) = l
\end{align*}
\]

- Fast Gradient Method (FGM) \((\text{Goodfellow et al. 2014})\):
  \[
  x_{\text{adv}} = x + \epsilon \ \text{sign} \ \nabla_x J_\theta(x, y).
  \]

- Basic Iterative Method (BIM), an iterative version of FGM \((\text{Kurakin et al. 2016})\):
  \[
  x_{\text{adv}}^0 = x, \ x_{\text{adv}}^i = x_{\text{adv}}^{i-1} + \epsilon \ \text{sign} \ \nabla_x J_\theta(x_{\text{adv}}^{i-1}, y).
  \]

- Jacobian-based Saliency Map Attack (JSMA) \((\text{Papernot et al. 2016})\).

- Optimization Based Attack (Opt.) \((\text{Carlini & Wagner 2017, Liu et al. 2016})\):
  \[
  \delta = \frac{1}{2} (\tanh(w) + 1) - x, \ min(\|\delta\|^2_2) + c \cdot f(x + \sigma).
  \]
Adversarial Subspaces & Dimensional Escape:

Adversarial Subspace: local subspace surrounding an adversarial example.

**Question:** What are the characteristics of adversarial subspaces?

**What we do know about adversarial subspaces?**
- Low probability and continuous regions, close to normal data submanifold, ...

**Intuitively:**
- Close in distance, yet semantically far from original data subspace.
- “Escape” to adversarial subspace with only a small perturbation.

**Dimensional Escape!**
Dimensionality and Adversarial Subspaces:

Intuition:
Adversarial subspaces are of high intrinsic dimensionality.

Dimensional Escape:
• Density will change
• Uncertainty will change
• Fundamentally, dimensionality increases!
• Revealed using estimators of intrinsic dimensionality.

Expansion Dimension:
• Two balls of differing radii $r_1$ and $r_2$, dimension $m$ can be deduced from ratios of volumes:
  \[
  \frac{V_2}{V_1} = \left(\frac{r_2}{r_1}\right)^m \Rightarrow m = \frac{\ln(V_2/V_1)}{\ln(r_2/r_1)}
  \]
• Related to the Expansion Dimension (Karger and Ruhl 2002, Houle et al. 2012)
• $V_1$ and $V_2$ estimated by the numbers of points contained in the two balls.
Local Intrinsic Dimensionality (LID):

**Definition (Local Intrinsic Dimensionality)**

Given a data sample $x \in X$, let $r > 0$ be a random variable denoting the distance from $x$ to other data samples. The *local intrinsic dimension* of $x$ at distance $r$ is

$$
\text{LID}_F(r) = \lim_{\varepsilon \to 0^+} \frac{\ln(F((1 + \varepsilon) \cdot r)/F(r))}{\ln(1 + \varepsilon)} = \frac{r \cdot F'(r)}{F(r)},
$$

wherever the limit exists.

- $F(r)$: cumulative distribution function.
- $F(r)$ is analogous to volume $V$ in Euclidean space, where $r_1$ and $r_2$ can be allowed to tend to a single value $r$. 
Estimation of LID:

Estimators of LID already available:

- Hill (MLE) estimator (Hill 1975, Amsaleg et al. 2015):
  \[
  \text{LID}(x) = -\left( \frac{1}{k} \sum_{i=1}^{k} \log \frac{r_i(x)}{r_k(x)} \right)^{-1},
  \]
  where \( r_i \) is the distance of \( x \) to its \( i^{th} \) nearest neighbor.

- Based on Extreme Value Theory:
  - Nearest neighbor distances are extreme events.
  - Lower tail distribution follows Generalized Pareto Distribution (GPD).

- Other estimators: e.g. Amsaleg et al. 2015, Gomes et al. 2008.
Interpretation of LID for Adversarial Subspaces:

- LID directly measures expansion rate of local distance distributions.

- The expansion of adversarial subspace is higher than normal data subspace.

- Adversarial examples are dimensionally outliers.
LID of Adversarial Subspaces:

We found:

- **Higher dimensionality**: In general, adversarial examples are of higher dimensionality (LID).
- **Minibatch efficiency**: Estimation of LID within a **minibatch** of 100 samples can help discriminate adversarial examples with high success rate, although larger batch size leads to further improvement.
- **Deeper layers**: LID difference is more pronounced at deeper layers.
Previous Work on Characterization of Adversarial Examples:

- Kernel Density (KD) (Feinman et al. 2017)

\[
KD(x) = \frac{1}{|X_c|} \sum_{s \in X_c} \exp \left( \frac{|F^{n-1}(x) - F^{n-1}(s)|^2}{\sigma^2} \right),
\]

\( X_c \): the set of samples in class \( c \);
\( F^{n-1}(x) \): the final hidden layer output.

- Bayesian Uncertainty (BU) (Feinman et al. 2017)

\[
BU(x) = \left( \frac{1}{L} \sum_{r=1}^{L} \| F_r(x) \| \right) - \left\| \frac{1}{L} \sum_{r=1}^{L} F_r(x) \right\|,
\]

\( F_r \): dropout randomized network;
\( L \): the number of randomization.
Experiments & Results:

Table 1: A comparison of the discrimination power (AUC score (%) of a logistic regression classifier) among LID, Kernel Density (KD), Bayesian Uncertainty (BU). AUC is computed for 5 attack strategies on 3 datasets. Best results are in **bold**.

</table>

LID characteristics of simple attacks can help to discriminate other attacks.
Integrating LID into the Adversarial Objective:

\[
\text{minimize } \|x_{adv} - x\|_2^2 + \alpha \cdot (\ell(x_{adv}) + \ell(\text{LID}(x_{adv})))
\]

It is difficult to explicitly generate adversarial examples residing in subspaces with low intrinsic dimensionality.
Conclusion:

- We characterize the dimensional characteristics of adversarial subspaces.
- Adversarial subspaces tend to possess higher intrinsic dimensionality than normal data subspaces.
- The dimensional characteristics (LID) can be leveraged to recognize adversarial examples residing in adversarial subspaces.

Future Work:

- Dimensionality-driven adversarial defense.
- Better estimation of LID: Larger batch size / neighborhood size.
- Better understanding of DNNs in terms of intrinsic dimensionality.

Limitations of LID for detection:

- We are focusing on characterizing adversarial subspaces instead of proposing a perfect detection method.
- We run additional experiments with DNNs trained using batch normalization, and tested the discrimination power of LID on attacks (in **bold**) analysed in *Lu et al. 2018* and *Athalye et al. 2018*.

We found that the LID will be more robust in regularized space (batch normalization), and it can be used to distinguish high confidence (40) attacks.

There are still space to improve LID based analysis to better understand adversarial spaces.
